

# *I2I Water*

## NEXT STEPS:

- A Breakdown of the top Priority

## “MAJ. NEAR TERM RECOMMENDATIONS (TO CCST AT 2/14 MEETING)”

1. Develop and Implement an integrated water information management system
2. Expand the use of monitoring technology and management practices

### Jude's “TOP FIVE” List:

1. **NEED FOR AN INTEGRATED WATER INFORMATION MGMT SYSTEM INCL  
NEED TO METER ALL WATER USE**

# From the Report's Executive Summary

1. **Develop and implement an integrated water information management system** for water supplies, uses, and quality including precipitation, runoff, and storage; for surface water, groundwater, and water use. *In situ* and remote monitoring devices and networks should be expanded and linked to an integrated data management system, or implemented where not available but needed. A common portal, such as DWR's Water PIE and UC Davis' HOBBS, that forms the cyber core of a flexible data and information-management program and capable of supporting data analysis, trending and scenario forecasting, should be developed with a common set of standards to link data collection from all sources with an integrated data management system.  
**Near-Term Actions:** The Governor and key agencies should immediately take the lead to form a consortium of parties, including the State Water Resources Control Board and the Department of Water Resources as well as a broad coalition of water experts in academia, trade organizations and non-governmental organizations with the specific goals of (1) evaluating what is realistic and practical to do in the short term, (2) designing the data collection and management system to accomplish the near-term task while maintaining capability for future flexibility and then (3) fully implementing this recommendation.

# *Actual ET comparison-spatial distribution – JJA 2007*

**Monthly ET (mm/month)**

*Results from MM5, with more realistic irrigation scheme, show significant improvement in capturing ET over irrigated Central Valley in California (compared to MODIS - ET estimates). MM5F overestimated.*

# *In a nutshell!*

- *ET Underestimation by MM5 control run is roughly about 10 million Ac-Ft of water/yr*
- *ET Overestimation by MM5 with “full-saturation” irrigation is about 6.5 Million Ac-Ft/yr*
- *Use of the realistic irrigation scheme results in only 1.5 Million Ac-Ft/yr of overestimation.*

## placed in Societal context :

**Roughly speaking, the amount of ET underestimation equals supply requirement of 13 million households and the overestimation covers the needs of 9 million households per year.**

# Data and Information Needs: Agriculture

## Agricultural water requirements and improvements in on-farm water use efficiency and water quality:

- Maintenance and expansion of California Irrigation Management and Information System (CIMIS) reference evapotranspiration ( $ET_0$ ) network
- Development of network of evapotranspiration monitoring sites in agricultural areas
- Satellite mapping of crop water requirements and crop evapotranspiration
- Development of statewide monitoring network for soil moisture and deep percolation / nitrate loss at agricultural sites

# *Regional Climate Trends and Scenarios: The Southwest U.S.*

## *USGCRP July 30, 2013*

### **Precipitation**

- Precipitation does not exhibit any obvious long-term trends for the Southwest U.S., except for fall, which shows a slight upward trend. Trends are not statistically significant for any season.
- The region experienced its wettest conditions in the 1980s and 1990s (coinciding with a shift in Pacific climate in 1976, after which El Niño became much more frequent), but has dried in the last decade.

### **Extremes**

- There is not a statistically significant trend in the occurrence of extreme precipitation events in the Southwest.

### Model Projections of an Imminent Transition to a More Arid Climate in Southwestern North America

Richard Seager,<sup>1\*</sup> Mingfang Ting,<sup>1</sup> Isaac Held,<sup>2,3</sup> Yochanan Kushnir,<sup>1</sup> Jian Lu,<sup>4</sup> Gabriel Vecchi,<sup>2</sup> Huei-Ping Huang,<sup>1</sup> Nili Harnik,<sup>5</sup> Ants Leetmaa,<sup>2</sup> Ngar-Cheung Lau,<sup>2,3</sup> Cuihua Li,<sup>1</sup> Jennifer Velez,<sup>1</sup> Naomi Naik<sup>1</sup>

How anthropogenic climate change will affect hydroclimate in the arid regions of southwestern North America has implications for the allocation of water resources and the course of regional

precipitation minus the evaporation ( $P - E$ ), averaged over this region for the period common to all of the models (1900–2098). The median, 25th, and 75th percentiles of the model  $P - E$  distribution and the median of  $P$  and  $E$  are shown. For cases in which there were multiple simulations with a single model, data from these simulations were averaged together before computing the distribution.  $P - E$  equals the moisture convergence by the atmospheric flow and (over land) the amount of water that goes into runoff.

In the multimodel ensemble mean, there is a transition to a sustained drier climate that begins in the late 20th and early 21st centuries. In the ensemble mean, both  $P$  and  $E$  decrease, but the former decreases by a larger amount.  $P - E$  is primarily reduced in winter, when  $P$  decreases and  $E$  is unchanged or modestly increased, whereas in summer, both  $P$  and  $E$  decrease. The annual mean reduction in  $P$  for this region, calculated from rain gauge data within the Global Historical Climatology Network, was 0.09 mm/day between 1932 and 1939 (the Dust Bowl drought) and 0.13 mm/day between 1948 and 1957 (the 1950s Southwest drought). The ensemble median reduction in  $P$  that drives the reduction in  $P - E$  reaches 0.1 mm/day in midcentury, and one quarter of the models reach this amount in the early part of the current century.

The annual mean  $P - E$  difference between 20-year periods in the 21st century and the 1950–2000 climatology for the 19 models are shown in Fig. 2. Almost all models have a drying trend in the American Southwest and the con-

## If these models are correct,

The Third Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) reported that the average of all the participating models showed a general decrease in rainfall in the subtropics during the 21st century, although there was also considerable disagreement among the models (1). Subtropical drying accompanying rising  $\text{CO}_2$  was also found in the models participating in the second Coupled Model Intercomparison Project (2). We examined future subtropical drying by analyzing the time history of precipitation in 19 climate models participating in the Fourth Assessment Report

(AR4) of the IPCC (3). The future climate projections followed the A1B emissions scenario (4), in which  $\text{CO}_2$  emissions increase until about 2050 and decrease modestly thereafter, leading to a  $\text{CO}_2$  concentration of 720 parts per million in 2100. We also analyzed the simulations by these models for the 1860–2000 period, in which the models were forced by the known history of trace gases and estimated changes in solar irradiance, volcanic and anthropogenic aerosols, and land use (with some variation among the models). These simulations provided initial conditions for the 21st-century climate projections. For each model,

Evapotranspiration (ET) is the loss of water to the atmosphere by the combined processes of evaporation (from soil and plant surfaces) and transpiration (from plants).
