## Appendix 1.D. Human Population Proximity analysis

## 1.D. 1 Overview

## Methods

## Storage well inventory

We obtained data for California wells from the California Division of Oil, Gas, and Geothermal Resources (DOGGR) using their dataset titled "All Wells." We intentionally used an older well dataset from 2015 (DOGGR, 2015; see reference list at end of this appendix) to reflect storage-well conditions before the incident at Aliso Canyon that started in October 2015. This was done with the goal of exploring the state of gas storage wells in California before changes brought on by the 2015 Aliso Canyon incident went into effect, including issuance of emergency regulations that would likely make 2016 and later well data unrepresentative of business as usual. We included all well data covering the 10 -year time period up to dataset's end, which included years 2006-2015.

We categorized wells as either "open" or "closed" to evaluate the likelihood of a well acting as a conduit for underground gas to reach the surface. This distinction is based on the presence or absence of an unplugged well. An "open" status reflects wells that have been drilled and completed, but have not been plugged. These correspond to well status values of "Active," "Idle," or "Buried" in DOGGR's records (DOGGR, 2014), and include both wells that are currently being used as well as abandoned wells. A "closed" status reflects all other wells, these either being wells that have been plugged, wells that were never drilled and completed in the first place, or wells with unknown status. In DOGGR's records, these correspond to well status values of "Plugged," "New," "Cancelled," or "Unknown" (DOGGR, 2014). We chose to include unplugged abandoned wells, but exclude plugged wells, because the literature to date suggests that while plugged wells can leak, they generally have leak rates that are significantly smaller than unplugged abandoned wells (Townsend-Small et al., 2016; Kang et al., 2016). Wells that were never spudded do not present any leakage pathways and thus pose no risk of gas migration.

To examine the risk of public health risks from multiple angles, we split the well dataset into two partially overlapping datasets which we labeled Tier 1 and Tier 2.

The Tier 1 dataset is focused specifically on the storage pool around each underground gas storage facility. It includes any open well that is located within a gas storage pool, defined as any pool into which gas was injected via a well with DOGGR's GS type designation indicating a gas storage injector or producer well (DOGGR, 2014), and determined through examination of annual injection databases (DOGGR, 2017). Since the wells within the Tier 1 designation are drilled directly into the gas storage pool, they post the most likely conduit for gas from the storage pool to migrate to the earth's surface. A loss of wellbore integrity is the most common cause of unintended gas migration, with common causes including casing
failure or cement failure (Ingraffea et al., 2014; Davies et al., 2014; Michanowicz et al., 2017).

The Tier 2 dataset represents a more conservative approach for public health and includes a broader set of criteria. This dataset includes all wells from Tier 1, and in addition it also includes any open well that is located within the same field area as the gas storage pool. While these wells are located outside of the storage pool, there is evidence from past gas storage events that wells within the same field area can provide a conduit for escaping gas. For instance, in 2001, in one of the most serious underground gas storage incidents to have occurred in the U.S., natural gas leaked from the Yaggy underground storage facility and migrated laterally underground over seven miles through geological units until it reached an abandoned well shaft in Hutchinson, Kansas, where the gas was able to migrate to the ground surface and cause a fatal explosion (Evans, 2009; Miyazaki, 2009; Yang et al., 2013). Pathways and failure modes are discussed further in Section 1.2 of this report. In addition, the set of Tier 2 wells serves as a proxy for where new storage wells might be located if future natural gas storage wells are drilled.

## Population data

We obtained demographic information for the California general, youth, and elderly population from the United States Census Bureau. We downloaded age data from the 2010 Decennial Census at the block level (U.S. Census Bureau, 2011) to determine population counts for the following variables: total population, under five years of age, and 75 years and older. The under-five population was tallied by summing the male and female under five population counts. The 75 years of age and older population was tallied by summing the male and female counts for the age ranges $75-79,80-84$, and 85 years and over.

## Sensitive receptors

We also collected data for a series of point locations we are calling "sensitive receptors," which are places where vulnerable subgroups congregate: schools and daycare centers for the youth population; residential elderly care facilities for the elderly population; and hospitals for the sick. These locations represent sites where a hazard may pose elevated risk to people, because of their vulnerability.

We obtained data for California schools and their enrollment from the California Department of Education (CDE). This included aggregating data for public schools (CDE, 2017a), private schools, (CDE, 2017b), and nonpublic, nonsectarian schools (CDE, 2017c). In California, nonpublic nonsectarian schools are a type of private school that provide specialized services to students with disabilities (CDE, 2016). With the goal of limiting the dataset to locations where children ages 5 to 18 congregate regularly, we delete all closed facilities and any other locations that did not fit this definition, including district or agency headquarters, adult education centers, preschools, medical facility education options, and virtual schools. We deleted any schools listed in multiple datasets or with duplicate

## Chapter 1

physical locations, in addition to any schools with a physical location outside of the state of California. The final dataset had 12,490 schools. All schools found in proximity to gas storage facilities in this analysis are currently open; none are pending.

Nonpublic nonsectarian schools and some private and public schools were missing enrollment data. We calculated the percentage of schools with enrollment data out of the total number of schools within each buffer distance for each facility, with a resulting range of $97.8-100 \%$ of the in-buffer schools with enrollment data. $86.4 \%$ of the storage facility buffer areas had $100 \%$ enrollment data for the schools within their boundaries. We obtained data for daycare centers from both the California Department of Social Services (CDSS) and the CDE. We defined daycares as sites that catered to care of groups of children less than five years of age, although we included sites that also included care for older children as long as the site was not also included in our schools dataset. From the California Department of Social Services (CDSS), we obtained datasets for child care centers and family child care homes CDSS, 2017a). These are distinguished by building type: child care centers are locations within commercial buildings, while family child care homes are located within parents' private homes (CDSS, 2017b). Within the schools datasets from the Department of Education, there were a number of sites that limited their enrollment to children of pre-school age. This was determined by a maximum grade level of Pre-K in the case of nonpublic nonsectarian schools (CDE, 2017c). With public school data, preschools were determined by the educational instruction level code, which listed grade levels taught and the school ownership code that described the type of school (CDE, 2017a). We deleted any duplicate daycares and/or preschools, as well as any facilities that were closed or had a status of inactive, leaving 26,799 remaining facilities. This dataset includes both currently open and pending daycare sites. Using the 5000 m buffer as a proxy to estimate the ratio of pending facilities, we estimate that $2.1 \%$ of daycare facilities have a pending status and are not currently open.

We downloaded residential elderly care locations from the CDSS (2017a). We deleted all closed sites. There were 8,056 remaining sites. Using the 5000 m buffer as a proxy to estimate the ratio of pending facilities, we estimate that $10.7 \%$ of residential elderly care locations have a pending status and are not currently open.

We obtained data for hospitals from the California Office of Statewide Health Planning and Development (OSHPD) from a dataset titled "Healthcare Facilities" (California OSHPD, 2017). To exclude other types of healthcare sites, we limited the dataset to only include facilities with a "Type" value of hospital. There were 629 facilities remaining. All of the hospitals in proximity to underground storage facilities are currently open.

## Spatial analysis

Using ESRI ArcGIS 10.3 software, we created geodesic buffers at 0, 100, 200, 400, 600, $800,1000,1600,2000,5000$, and 8000 meters around the storage facility boundaries. The 0 m buffer is the same thing as the storage facility boundary layer. The buffers used in this analysis are designed to encompass populations within various proximities to natural gas storage and associated emissions, with the assumption that exposure to emissions will be the highest at the 0 m buffer and will continue at decreasing exposures through the remaining buffers as distance from development increases. This assumption is supported by analysis of resident complaint calls summarized by the Los Angeles County Department of Public Health (LACDPH) in response to the Aliso Canyon incident, which found that the likelihood of reported health symptoms, including headache, nausea, nosebleeds, and respiratory problems, among other symptoms, was substantially greater for residents that lived $\leq 3$ miles from the gas leak ( $55.8 \%$ of complaints) compared with residents that lived $>5$ miles from the gas leak ( $16.8 \%$ of complaints) (LACDPH, 2016). For risk in particular of well blowouts, there is evidence that, in the case of breach blowouts, the emission points to atmosphere (surface fractures or craters) typically do not exceed a distance of 600 m from the wellhead of the well that sustained the subsurface blowout (Jordan and Benson, 2009).

We added a final buffer utilizing results from the air dispersion data. This buffer represents the largest distance the 0.50 quantile level reaches outwards from the edge of each storage facility well boundary. Since the area around each UGS facility has different wind patterns, the maximum distance varies from site to site. To calculate this distance for each UGS, we calculated the minimum bounding geometry of each 0.50 quantile level polygon produced from the air dispersion modeling. We then measured the distance from the outermost wells to the minimum bounding geometry and determined which distance (from which outermost well) was the greatest at each facility. Over the facilities, these distances ranged from $7,977 \mathrm{~m}$ at Lodi Gas to $12,037 \mathrm{~m}$ at Montebello. We applied these distances to radial buffers, with each site having a unique buffer distance to produce the QL50 buffer layer. We only calculated the total number of people for this buffer; we did not calculate vulnerable population counts or sensitive receptors.

To calculate the number of total people, under five, and 75 years of age and older living within each buffer distance, we intersected the Census block polygons with each of the ten buffers, and then allocated block-level counts to areas within each buffer polygon by calculating the percentage of each census block residing with each aggregated buffer polygon, applying these percentages to population counts. This method is commonly known as areal estimation. We summed the calculated population counts over each buffer distance and over each oil and gas variable of interest.

There were 11,736 family child care homes from the daycare centers dataset that lacked either xy coordinates or street addresses, but did include spatial location data at the zip code level. To calculate the number of daycares for which we had zip-code level counts, we needed to take a different approach than was used to calculate the rest of the facility

## Chapter 1

counts. For these sites, we performed linear regressions with daycare count as the dependent variable, and total population, under five, and age fourteen and younger, and land area in turn as the independent variables to determine which variable is the most strongly correlated with number of daycares within a zip code. Total population was the most strongly correlated with daycare count; therefore, we weighted daycare counts by population counts to estimate the number of daycares within each buffer.

For all sensitive receptor locations with xy coordinates, we imported them into ArcGIS using these coordinates. We geocoded all sites with street addresses using the World Geocode Service through ArcGIS Online. We then spatially joined schools, daycare facilities, elderly care facilities, and hospitals with each storage facility buffer which resulted in counts for each population aggregation site that are located within each buffer distance around each gas storage facility. We summed enrollment counts for all schools located within each storage facility buffer to calculate the total number of children enrolled in schools in proximity to each UGS facility.

To evaluate populations downwind of the gas storage facilities, we calculated spatial extents for the downwind areas that would capture air emissions from the gas facilities. These spatial extents were divided into six quantile levels ( $0.65,0.75,0.85,0.95,0.99$, and 0.999 ) with each quantile level representing the percentage of the cumulative distribution that would fall outside of its spatial extent. For example, the 0.65 quantile level polygon shows the area for which $65 \%$ of the cumulative distribution would fall outside of, therefore $35 \%$ of the cumulative distribution would fall within. Like with the radial buffers, we intersected Census block polygons with each of the quantile level polygons and used areal estimation to estimate the total population residing within each quantile level for each storage facility.

## Full results tables

Tables 1.4.C-1 through 1.4.C-3 provide population and sensitive receptor results for each individual facility and buffer distance or quantile level area.
